Abstract:- For identification of a particular human being signatures prove to be an important biometric. The signature of a person is an important biometric attribute of a human being which can be used to authenticate human identity. However human signatures can be handled as an image and recognized using computer vision and neural network techniques. With modern computers, there is need to develop fast algorithms for signature recognition. There are various approaches to signature recognition with a lot of scope of research. In this paper, off-line signature recognition & verification using neural network is proposed, where the signature is captured and presented to the user in an image format. Signatures are verified cbn based on parameters extracted from the signature using various image processing techniques. This paper presents a proposed method for verifying offline-signatures .Novel features are used for classification of signatures. A Feed Forward Neural Network will be used for verifying signatures and to determine its accuracy.

Keywords - Signature, Athentication, Feed Forward Neural Network, biometric, offline-signature recognition & verification.

I. INTRODUCTION

Within the field of human classification, the procedure of biometrics is emergent because of its distinctive properties such as hand geometry, iris scan, fingerprints or DNA. The use of signatures has been one of the more opportune methods for the recognition and verification of human beings. A signature may be termed a behavioural biometric, as it can modify depending on many essentials such as: frame of mind, exhaustion, etc. The exigent aspects of automated signature recognition and verification have been, for a long time, a true impetus for researchers. Research into signature verification has been energetically pursued for a number of years [1] and is still being explored (especially in the off-line mode) [2]. On-line verification must be differentiated from off-line verification, as the number of features, which may be extracted from on-line mediums, surpass those obtained from off-line verification i.e. time, pressure and velocity can be extracted from on-line modes of verification [3]. Prior approaches, such as that based on fuzzy modeling and the employment of the Takagi-Sugeno model, have been projected using angle features extracted. from a box approach to verify and identify signatures [4]. Also, The GSC (Gradient, Structural and Concavity) trait extractor

provided outcome as high as: 78% for verification and 93% for identification [5]. Various classifiers, such as Support Vector Machines (SVMs) and Hidden Markov Models (HMMs), have also been successful in off-line signature verification; SVMs providing an overall enhanced outcome than the HMM-based approach [6]. Study into person identification/verification, including physical character, fingerprint and signature examination has also been investigated [7].

In the field of pattern recognition, choosing a dominant set of features is crucial for both the application and the classifier. H. Lv *et al* used the direction distribution, moment feature, stroke width distribution and grey distribution to carry out signature verification [8]. Prior work using the Modified Direction Feature (MDF) generated encouraging results, reaching an precision of 81.58% for cursive handwritten character identification [9]. A problem of personal verification and identification is an actively growing area of research. The methods are numerous and are based on different personal characteristics; voice, lip movement, hand geometry, face, odor, gait, iris, retina and fingerprint are the most commonly used authentication methods. All these

psychological and behavioral characteristics are called biometrics. The driving force of the progress in this field is above all, the growing role of the internet and electronic transfers in modern society. Therefore considerable number of applications is concentrated in the area of electronic commerce and electronic banking systems [10]. The method of signature verification reviewed in this paper benefits the advantage of being highly accepted by potential customers. The use of the signature has a long history which goes back to the appearance of writing itself [11]. Utilization of the signature as an authentication method has already become a tradition in the western civilization and is respected among the others. The signature is an accepted proof of identity of the person in a transaction taken on his or her behalf. Thus the users are more likely to approve this kind of computerized authentication method [12]. Signature verification systems differ in both their feature selection and their decision methodologies. More than 40 different feature types have been used for signature verification [13]. Signature recognition and verification involves two separate but strongly related tasks: one of them is identification of the signature owner, and the other is the decision about whether the signature is genuine or forged. Also, depending on the need, signature recognition and verification problem is put into two major classes: (i) On-line signature recognition and verification systems (SRVS) and (ii) Off-line SRVS. On-line SRVS requires some special peripheral units for measuring hand speed and pressure on the human hand when it creates the signature. On the other hand, almost all Off-line SRVS systems rely on image processing and feature extraction techniques [14].

A. Types of Signature Verification

Based on the definitions of signature, it can lead to two different approaches of signature verification.

1) Off-Line or Static Signature Verification Technique:

This approach is based on static characteristics of the signature which are invariant [15]. In this sense signature verification, becomes a typical pattern recognition task knowing that variations in signature pattern are inevitable; the task of signature authentication can be narrowed to drawing the threshold of the range of genuine variation. In the offline signature verification techniques, images of the signatures written on a paper are obtained using a scanner or a camera.

2) On-line or Dynamic Signature Verification Technique:

This is the second type of signature verification technique. This approach is based on dynamic characteristics of the process of signing. This verification uses signatures that are captured by pressure sensitive tablets that extract dynamic properties of a signature in addition to its shape. Dynamic features include the number of order of the strokes, the overall speed of the signature and the pen pressure at each point that make the signature more unique and more difficult to forge. Application areas of Online Signature Verification include protection of small personal devices (e.g. PDA, laptop), authorization of computer users for accessing sensitive data or programs and authentication of individuals for access to physical devices or buildings [16].

B. Nature of Human Signature

It is supposed that the features of the process of signing originate from the intrinsic properties of human neuromuscular system which produces the aforementioned rapid movements. Knowing that this system is constituted by a very large number of neurons and muscle, fibers is possible to declare based on the central limit theorem that a rapid and habitual movement velocity profile tends toward a delta-log normal equation [12]. This statement explains stability of the characteristics of the signature. Thus, the signature can be treated as an output of a system obscured in a certain time interval necessary to make the signature. This system models the person making the signature [17].

C. Types of Forgeries

The main task of any signature verification system is to detect whether the signature is genuine or counterfeit. Forgery is a crime that aims at deceiving people. Since actual forgeries are difficult to obtain, the instrument and the results of the verification depend on the type of the forgery [11]. Basically there are three types that have been defined: **Random forgery**: this can normally be represented by a signature sample that belongs to a different writer i.e. the forger has no information whatsoever about the signature style and the name of the person. **Simple forgery**: this is a signature with the same shape or the genuine writer's name. **Skilled forgery**: this is signed by a person who has had access to a genuine signature for practice [16].

II. RELATED WORK

As signatures continue to play an important role in financial, commercial and legal transactions, truly secured authentication becomes more and more crucial. This section presents the current approaches for verification of

signatures in offline mode. To perform verification or identification of a signature, several steps must be performed. After preprocessing all signatures from the database by converting them to a portable bitmap format, their boundaries are extracted to facilitate the extraction of features using MDF. Verification experiments are performed with neural-based classifiers. Experiments have been performed with the “Grupo de Procesado Digital de Senales” (GPDS) signature database [10]. The boundary of each signature must be extracted prior to the feature extraction process. The features extracted must be appropriate for both the application and the classifier used. MDF has been used to extract features for the signature verification problem. This technique employs a hybrid of two other feature extraction techniques, Direction Feature (DF) and the Transition Feature (TF). Another features like centroid, tri surface, length feature, sixfold surface feature, best fit feature were extracted by this method[9].

The next approach presents a set of geometric signature features for offline automatic signature verification based on the description of the signature envelope and the interior stroke distribution in polar and Cartesian coordinates. The features have been calculated using 16 bits fixed-point arithmetic and tested with different classifiers, such as hidden Markov models, support vector machines, and Euclidean distance classifier. The experiments have shown promising results in the task of discriminating random and simple forgeries. The geometrical features proposed by this method is based on two vectors which represent the envelope description and the interior stroke distribution in polar and Cartesian coordinates [18].

The next approach for Off-line Signature Verification is based on Fusion of Grid and Global Features Using Neural Networks. The global and grid features are fused to generate set of features for the verification of signature. The test signature is compared with data base signatures based on the set of features and match/non match of signatures is decided with the help of Neural Network. The performance analysis is conducted on random, unskilled and skilled signature forgeries along with genuine signatures [19].

This approach is based on compression neural networks; It is a novel robust technique for the off-line signature verification problem in practical real conditions is presented. The technique is based on the use of compression neural networks, and in the automatic generation of the training set from only one signature for each writer. This methods incorporates a new kind of acceptance/rejection rule, which is based on the similarity between subimages or positional cuttings of a test signature and the corresponding representation stored in the class compression network[20].

This approach uses principle component analysis for off-line signature identification method based on Fourier Descriptor (FDs) and Chain Codes features. Signature identification classified into two different problems: recognition and verification. In recognition process Principle Component Analysis was used. In verification process multilayer feed forward artificial neural network was used[21].

III. PROPOSED METHODOLOGY

To perform verification or identification of a signature, several steps must be performed. After preprocessing all signatures from the database ,then by enhancing the image various features will be extracted. Verification experiments are performed with neural-based classifiers. The present work has to be carried out in two steps. Initially a set of signatures are obtained from the subject and fed to the system. These signatures and preprocessed then the preprocessed images are used to extract relevant features like Extent, Solidity, Number of objects, Majoraxislength, Equivdiameter, Area, Convex area, Orientation and Euler number that can distinguish signatures of different persons. These are used to train the system. The proposed methodology or procedure for classification of signature image are as follows:

1. Acquire the Signature images.
2. Enhance image to remove noise and blurring.
3. Extract the various features.
4. Use these features to train the system using Feed Forward neural network.
5. Employ unknown Signature image to extract its features.
6. Perform the pattern matching with data set.
7. Do the classification
8. Take decision as originals or forgeries.

For implementation of signature verification a database of about 15-20 individuals actual signatures and also there forged signatures are required.

The below figure describes the work flow of signature verification process. For correctness of this first the signature is taken and care should be taken that is it should be free from noise & other ambiguities. Then matching process is used and depending on the results of the matched process final results are obtained that is whether the signature is original or forged one.

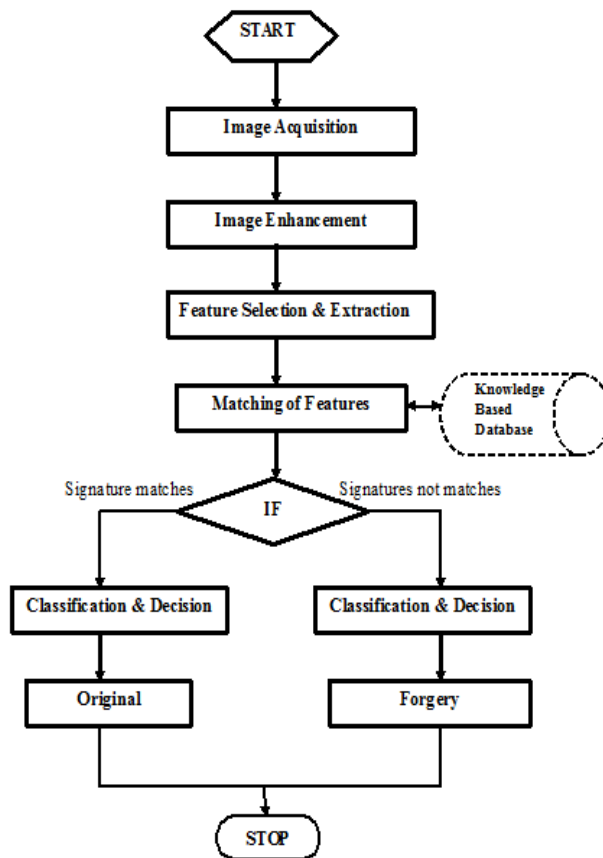

Figure 1. Workflow of signature verification system

IV. CONCLUSION

This paper is focused on signature verification methods. Signatures are verified based on parameters extracted from the signature using various image processing techniques. This paper will be completed when the utility of signature verification is shown i.e it helps in detecting the exact person and it provides more accuracy of verifying signatures as compared to prior works . For verification of signatures some novel features needs to be extracted. For implementation of above this paper uses Feed Forward Neural Network (FFNN) for recognition and verification of signatures of individuals.
