Abstract: Recommender systems play an important role in filtering and customizing the desired information. Recommender system are divided into 3 categories i.e collaborative filtering , content-based filtering, and hybrid filtering and they are the most adopted techniques being utilized in recommender systems. In this paper describes about various limitations of current recommendation methods such as cold-start problem ,Gray-sheep problem and discuss possible extensions that can improve recommendation capabilities in range of applications extensions such as, improvement of understanding of users and items incorporation of the contextual information into the recommendation process, support for multi-criteria ratings. The paper consist the survey of various hybrid filtering to overcome the drawbacks and extensions of a forementioned techniques .

Keywords: Recommender system, Collaborative filtering(CBF) , Content filtering(CF), Hybrid filtering, Coldstart, Graysheep.

I. INTRODUCTION

In everyday life, people rely on recommendations from other people by spoken words, reference letters, news reports from news media, general surveys, travel guides etc so recommendations plays an important role in finding the best items. A recommender system is the information filtering that applies data analysis techniques to the problem of helping customers find the products they would like to purchase by producing a predicted likeness score or a list of recommended products for a given customer. Recommender systems work from a specific type of information filtering system technique that attempts to recommend information items (movies, TV program/show/episode,music, books, news, images, web pages, scientific literature etc.) or social elements (e.g. people, events or groups) that are likely to be of interest to the user[1].

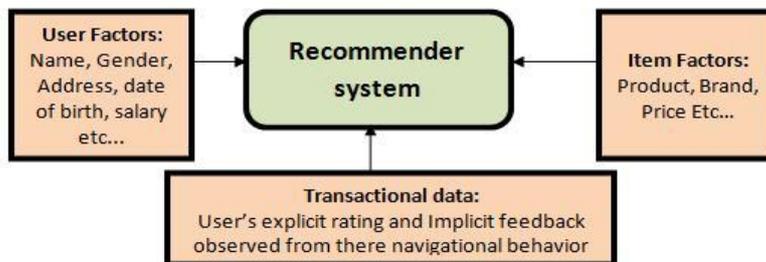

Fig:1 Recommender System[6]

The recommender system also compare the user profiles and seek to predict the ratings. With the help of Recommender systems are filtering and sorting data can be easily done. Moreover the Recommender system use opinions about the community of users and to determine content of interest using certain rules extractions. Recommendation systems are classified into 3 approaches i.e collaborative, contentbased or knowledge-based method to have a better recommendation. Each recommendation systems have some strategy to recommend better, the most useful strategies are listed below

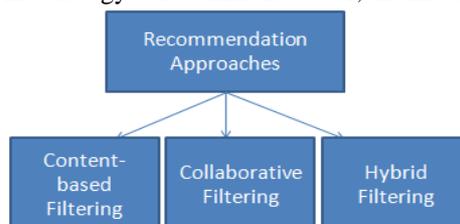

Fig:2 Recommendation Approaches

A. Collaborative based Recommendation systems

Collaborative filtering Algorithm recommender system became one of the most researched techniques of recommender systems .if users shared the same interests in the past, they will also have similar tastes in the future. So,

for example, if user A and user B have a purchase history that overlaps strongly and user A has recently bought an item that B has not yet been, the basic rationale is to propose this item also to B. The collaborative filtering technique recommends items based on user-based approach and item-based approach[2].

1) User-Based Approach:

In the User-based approach the user plays an important role. If certain majority of the customer have same taste then they join into the one group. Recommendations are given to user based on evaluation of items by other users form the same group, with whom he/she shares common preferences. If the item was positively rated by the community, it will be recommended to the user.

2) Item-Based Approach:

Here in Item-Based Approach the items play an important role. Recommendations are based on evaluation of items. The system generates recommendations with items in the neighborhood that a user would prefer.

Table:1 Advantages and Drawbacks of CBF &CF [3]

Technique	Advantage	Disadvantage
Collaborative filtering (CF)	A. Can identify cross-genre niches.	I. New user ramp-up problem
	B. Domain knowledge not needed.	J. New item ramp-up problem
	C. Adaptive: quality improves over time.	K. 'Gray sheep' problem
	D. Implicit feedback sufficient	L. Quality dependent on large Historical data set.
		M. Stability vs. plasticity problem
Content-based (CN)	B, C, D	I, L, M

B. Content Based Recommendation System

Here in Content-based recommender systems deals with profiles of users that are created at the beginning. A profile has information about a user and his taste which is based on how user rates the items. In the recommendation process, the engine compares items that were already rated by user with items he did not rate and looks for similarities. Those items that are mostly similar to the positively rated ones, and the one which are positively rated by the users are recommended to the users[2].

In the context of content-based recommendation, the following questions that arise :

- How to determine which items match, or are at least similar to or compatible with, a user's interests?
- Which techniques can be used to automatically extract or learn the item descriptions ?

C. Hybrid Based Recommendation System

Here in Hybrid Recommendation it is a combination of both collaborative approach and content based approach. With the help of Hybrid Recommendation different types of problems can be easily overcome the problem such as Cold-Start problem can be handled using the hybrid recommendations[2].

The combination of approaches can proceed in different ways:

- 1) How implementation of algorithms take place??.
- 2)How to utilize some rules of content filtering in collaborative filtering??.
- 3) How to extract rules in the Hybrid recommendations?

II. CHALLENGES AND ISSUES

A. Cold-Start Problem

Its difficult to give recommendations to new users because his profile is almost empty and he has not rated any items so the taste of user remains unknown to the system so this type of the problem is called as coldstart problem. In some recommender systems this problem can be solve with the survey at the time of creating a profile. Another problem is when user has not rated before when new to the system. Both of these problems can be overcome with the help of hybrid approaches[2].

B. Data-Sparsity

Sparsity is the problem of lack of information. Suppose we have a huge amount of users and items but user have rated only few items. If a user has evaluated only few items then its difficult to determine the taste of the user. so to overcome this we use collaborative and hybrid approach to create neighborhoods of users based on their profiles.

C. Scalability

Due to increase of numbers of users and items, the system needs more resources for processing information and forming recommendations. Majority of resources is consumed with the purpose of determining users with similar tastes, and goods with similar descriptions. This problem is also solved by the combination of various types of filters and physical improvement of systems.

D. Gray Sheep

Gray sheep problem means where user doesnot consistently agree or disagree to the group of the people and due to this reason for such user recommendation seems to be difficult[7].

E. Explainability:

Explainability is another important aspect of recommender systems. An incomplete reasoning such as “you will like this item because you liked those items” due to this recommendations of items will be difficult.

III. DIFFERENT HYBRIDIZATION METHODS

Hybrid recommender systems combine two or more recommendation techniques for better performance with some drawbacks of any individual one[7].

1) Weighted Method

Here in Weighted method scores of several recommendations are combined together and it help to produce the single recommendation. The example of weighted method is P-TANGO system that uses hybrid Recommendations. Here first of all equal weight is assigned to both content and collaborative recommenders but gradually adjust the weights as the prediction of ratings are confirmed. Pazzani’s combination hybrid does not use numeric scores, but rather use the output of each recommender as a set of votes, which are then combined in a consensus scheme.

2) Switching Method

Here in Switching method system uses some criterion to switch between recommendation techniques. The DailyLearner system uses a content/collaborative hybrid in which a content- based recommendation method is applied first. If the content-based system cannot make a recommendation with sufficient confidence, then a collaborative recommendation is attempted. this switching hybrid doesnot completely avoid problem.

3) Mixed Method

When large recommendations take place the Mixed method come into the action. here in this method is used in Television System used. First of all content based method is used for textual description of tv-shows and use of collaborative method for finding the preferences of the user and Recommendations from the two techniques lead to suggest a final program. with the help of this mixed method new item -start up problem can be overcome: the content-based component can be relied on to recommend new shows on the basis of their descriptions even if they have not been rated by anyone. It does not get around the “new user” start-up problem, since both the content and collaborative methods need some data about user preferences to get off the ground, but if such a system is integrated into a digital television, it can track what shows are watched (and for how long) and build its profiles accordingly.

4) Feature combination

In Feature combination the features from different recommendation data sources are used together into a single recommendation algorithm. feature combination hybrid lets the system consider collaborative data without relying on it exclusively, so it reduces the sensitivity of the system to the number of users who have rated an item. Conversely, it lets the system have information about the inherent similarity of items that are otherwise opaque to a collaborative system.

5) Cascade

Here in Cascade method it involves the stage process In this technique, one recommendation technique is employed to produce a ranking of candidates and a second technique refines the recommendation from the candidate set. The restaurant recommender EntreeC, described below, is a cascaded knowledge-based and collaborative recommender. Like Entree, it uses its knowledge of restaurants to make recommendations based on the user’s stated interests. The recommendations are placed in buckets of equal preference, and the collaborative technique is employed to break ties, further ranking the suggestions in each bucket.

6) Feature Augmentation

To improve the performance of a core system Feature Augmentation is used. For example Libra System makes content-based recommendations of books based on data found in Amazon.com, using a naïve-bayes text classifier and this help in

finding the quality of books. In Feature Augmentation One technique is used to produce a rating of an item and that information is then incorporated into the processing of the next recommendation technique. so the difference between the Cascade and augmentation are as follows: in feature augmentation the feature used by second recommendation is the one which is the output of the first one where as in cascading second recommender doesnot use the output of first one but the results of the two recommenders are combined in a prioritized manner.

7) Meta-level

Here two recommendation techniques can be merged by using the model generated by one as the input for another. The difference between the meta-level and augmentation is that in augmentation output of first recommender is used as input for second one where as in meta-level the entire model will be consider as a input for the second one . The first meta-level hybrid was the web filtering system Fab .

IV. HYBRID APPROACHES

Different approaches that are used for classifying the hybrid approaches they are as follows[5]:

1. Combining separate recommenders.

In this method to implement the hybrid recommendations we have to implement separate collaborative and content methods Thenafter, we can combine the outputs (ratings) obtained from individual recommender systems into one final recommendation using either a linear combination of ratings or a voting scheme . For example:Daily Learner System.

2. Adding content-based characteristics to collaborative models.

This type is used to overcome the problem of Sparsity.To overcome the problem of sparsity , in this approach the similarity between two user is calculated between the content based profiles and not commonly rated items. Another benefit of this approach is that users can be recommended an item not only when this item is rated highly by users with similar profiles, but also directly, i.e., when this item scores highly against the user's profile.

3. Adding collaborative characteristics to content-based models.

The most popular approach is to use some dimensionality reduction technique on a group of content-based profiles. For example it use latent semantic indexing (LSI) to create a collaborative view of a collection of user profiles, where user profiles are represented by term vectors , resulting in a performance improvement compared to the pure content-based approach.

4. Developing a single unifying recommendation model.

Many researchers have followed this approach now a days. For instance, one approach propose to use content-based and collaborative characteristics (e.g., the age or gender of users or the genre of movies) in a single rule-based classifier. another approach propose a unified probabilistic method for combining collaborative and content-based recommendations, which is based on the probabilistic latent semantic analysis. Yet another approach proposed , where Bayesian mixed-effect regression models are used that employ Markov chain Monte Carlo methods for parameter estimation and prediction.

V. EXTENDING CAPABILITIES OF RECOMMENDER SYSTEMS

Recommender system can be extended in several ways that include the improving the understanding of users and items, incorporating the contextual information into the recommendation process, supporting multi-criteria ratings, and providing more flexible and less intrusive types of recommendations. This section describe about the proposed extensions and also identify various research opportunities for developing them[4].

Table:2 Comparasion of Different Recommendation approaches

Recommendation Approach	Recommendation Technique	
	Heuristic-based	Model-based
Content-based	Commonly used techniques: <ul style="list-style-type: none"> • TF-IDF (information retrieval) • Clustering Representative research examples: <ul style="list-style-type: none"> • Lang 1995 • Balabanovic & Shoham 1997 • Pazzani & Billsus 1997 	Commonly used techniques: <ul style="list-style-type: none"> • Bayesian classifiers • Clustering • Decision trees • Artificial neural networks Representative research examples: <ul style="list-style-type: none"> • Pazzani & Billsus 1997

V. CONCLUSION

Recommendation System plays an important role over recent years where various method such as content ,collaborative ,and hybrid method are proposed .This paper mainly describes various limitations in recommendation system. The paper mainly consist of various hybridization methods like weighted method, which is used to overcome the certain limitations Moreover, paper also describes about the various approaches regarding the hybridization and it will help to know wether which approach to be used for hybridization .
